Cellular Automaton on Hanoi Graphs

Geethan Pfeifer

January 10, 2025

1 Introduction

This document informally describes cellular automaton on Hanoi Graphs, which resemble Sierpinski Triangles, and also a basic implementation in Golly.

2 Hanoi Graphs

Read https://mathworld.wolfram.com/HanoiGraph.html for an introduction to Hanoi Graphs.

3 Structure of Hanoi Graphs

Every Hanoi graph has 3 vertices of degree 2 (denote these vertices as *corner* vertices), with every other vertex having degree 3 (denote these vertices as *inner* vertices.)¹ Each inner vertex is part of a 3-clique and a 2-clique.

4 Neighbourhood

Consider a Hanoi Graph H_n as you would typically on a plane.

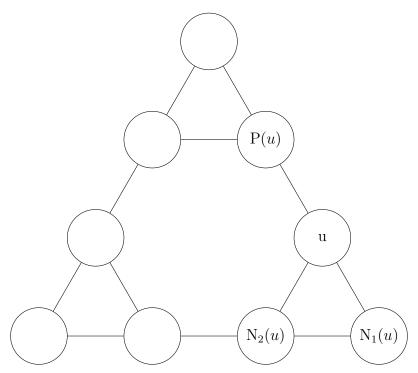

For each inner vertex u, consider the vertex it forms a 2-clique with as P(u). Consider the vertices it forms a 3-clique with as $N_1(u)$, $N_2(u)$, with $N_1(u)$ being clockwise to u and $N_2(u)$ being counterclockwise to u.

Define the neighbourhood of u as the tuple $(u, P(u), N_1(u), N_2(u))$.

¹These are not standard definitions, I'm just defining them as such for convenience.

4.1 Example

For example, consider H_2 below, with labelled inner vertex u, and labelled P(u), $N_1(u)$, and $N_2(u)$.

4.2 Note

On a Hanoi graph, for a inner vertex u with P(u), $N_1(u)$, and $N_2(u)$ also inner vertices, P(P(u)) = u, $N_1(N_1(N_1(u))) = u$, and $N_2(N_2(N_2(u))) = u$.

5 Cellular Automaton

Take a Hanoi Graph $H_n = (V, E)$, with inner vertices I. Let Q be the set of states.

Define a transition function $\delta: Q^4 \to Q$.

Define $\operatorname{CA}_0(u): V \to Q$.

For t > 0, define:

$$CA_t: V \to Q_t$$

$$CA_{t}(u) = \begin{cases} \delta(CA_{t-1}(u), CA_{t-1}(P(u)), CA_{t-1}(N_{1}(u)), CA_{t-1}(N_{2}(u))), & u \in I \\ \text{undefined}, & u \notin I \end{cases}$$

For convenience, we can define $CA_t(u) = CA_0(u), u \notin I$, but other options are possible.

Concisely, the state of an inner vertex u depends on the states of its neighbours and itself in the previous generation, and the state of corner vertices is undefined.

6 Elementary Automaton

Take $Q = \{0, 1\}$. Clearly, there are $2^{2^4} = 65536$ possible transition functions. We can number them with 16-bit integers, with the m-th bit of n being the value of $\delta_n(m_0, m_1, m_2, m_3)$, where $m_3 m_2 m_1 m_0$ is the binary representation of m. Call δ_n Sierpinski \mathbf{n}^2

6.1 Example

For example, take Sierpinski 49980.

The binary representation of 49980 is 1100001100111100_2 .

This is the transition table:

m	$\ \operatorname{CA}_{t-1}(u)\ $	$\operatorname{CA}_{t-1}(\operatorname{P}(u))$	$\operatorname{CA}_{t-1}(\operatorname{N}_1(u))$	$\operatorname{CA}_{t-1}(\operatorname{N}_2(u))$	$CA_t(u)$
0	0	0	0	0	0
1	\parallel 1	0	0	0	0
2	0	1	0	0	1
3	1	1	0	0	1
4	0	0	1	0	1
5	1	0	1	0	1
6	0	1	1	0	0
7	1	1	1	0	0
8	0	0	0	1	1
9	1	0	0	1	1
10	0	1	0	1	0
11	1	1	0	1	0
12	0	0	1	1	0
13	1	0	1	1	0
14	0	1	1	1	1
15	\parallel 1	1	1	1	1

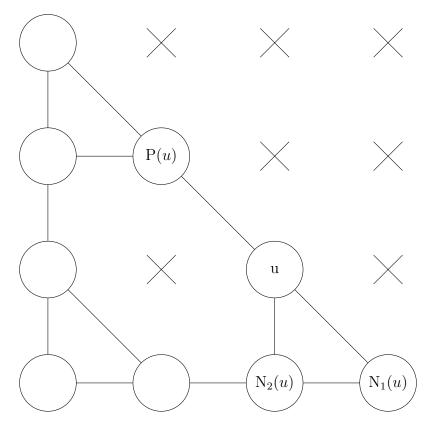

(This rule updates to the XOR sum of the neighbours of a vertex.)

²Perhaps Hanoi n is a better name, but I already named it Sierpinski n in my Golly implementation.

7 Golly

7.1 Representation on a 2-D grid

If you "skew" the planar representation of a Hanoi Graph slightly it fits nicely on a 2D grid. For example, we can "skew" the graph in 4.1 as such:

Each cross represents an empty square.

7.2 Advantages of this representation

The neighbourhood of an inner vertex u as defined in 4 (and their states) can be determined solely by the Moore neighbourhood of u on the 2D grid, meaning that we can create Golly rules for it.³

Also, this representation of the Hanoi Graph can be easily generated by Wolfram 60.

7.3 Generating golly rules

sierpinskirulegen generates a Golly rule corresponding to a specified Sierpinski rule. In the rule, state 0 corresponds to an empty square, states 1 and 2 correspond to states 0 and 1 as per 6 respectively, and corner vertices are static.

³I was shocked to discover that there are very few neighbourhoods supported by Golly! I initially planned to use a different representation, but that representation wouldn't be possible with a neighbourhood supported by Golly.

8 Future work

- Develop an "infinite Hanoi graph" such that all vertices are inner.
- Develop analogues of tori such that all vertices are inner.
- Create a custom program for cellular automaton on fractal patterns—Golly is quite limited.
- Develop the concept of a "direction". (How would spaceships work with these cellular automaton? Are they even possible?)
